
Subject: Tunneling Effects Assessment (Final Draft)

Project feature: Tunnels

Prepared for: California Department of Water Resources (DWR) / Delta Conveyance Office (DCO)

Prepared by: Delta Conveyance Design and Construction Authority (DCA)

Copies to: File

Date/Version: December 23, 2021

Reference no.: EDM_TS_CE_TMO_Tunneling-Effects-Assessment_000949_V03_FD_20211223

1. Introduction and Purpose

The Delta Conveyance Project (Project) would include intakes along the Sacramento River between the confluences with American River and Sutter Slough and a tunnel between the intakes and a forebay at the downstream terminus of the main tunnel referred to as the Southern Forebay. Water would either flow by gravity or be lifted by the South Delta Pumping Plant from the tunnel into the Southern Forebay. Discharge from the Southern Forebay would occur through the Southern Forebay Outlet Structure, at the south end of the reservoir, into the South Delta Conveyance facilities (SDCF) for connection to the existing State Water Project Harvey O. Banks Pumping Plant (Banks) and Central Valley Project C.W. Bill Jones Pumping Plant (Jones).

The purpose of this technical memorandum (TM) is to summarize the results of a preliminary settlement analysis for the Project along two tunnel alignments, the Central and Eastern corridors. The TM also discusses the preliminary analysis of TBM vibrations that can be expected along the main tunnel alignment. The analysis involved estimating ground surface settlements along with the settlement of key infrastructure the tunnel crosses, which are reported herein. The settlement analysis is used to begin assessing the potential mitigation measures that may be needed for the existing structures, levees, utilities, and roadways resulting from the proposed tunnel excavation method. The evaluation presented in this TM for the purposes of the environmental impact report is based upon a 36-foot ID main tunnel which would be installed with at least two-tunnel diameters of cover. During final design phase, specific cover depths would be determined based upon site-specific geotechnical information and tunnel profile.

Surface settlements resulting from tunneling activities depend on the following considerations, among others:

- Geological conditions
- Tunnel excavation diameter
- Amount of groundcover
- Tunnel excavation method
- Ground support installed
- Backfill grouting of segmental lining
- Workmanship of the tunnel contractor

This TM addresses the key parameters required to estimate tunnel-induced settlement and provides preliminary settlement values at key project locations (based solely on proposed construction activities). It does not address settlement due to liquefaction, consolidation, or other long-term considerations.

The information in this TM is based on conceptual engineering information at time of preparation and will be modified prior to publication of the Engineering Project Report. This TM considers a range of project design flow capacities, including 3,000, 4,500, 6,000, and 7,500 cubic feet per second (cfs). The internal diameter of the tunnels would vary depending on the project design flow capacity however, it is anticipated to range between 26 feet and 40 feet.

The elevations presented in the TM should be considered approximate. The vertical datum used for this project is the North American Vertical Datum of 1988 (NAVD 88). Once the final alignment, invert elevation (at the bottom of the tunnel), and tunnel diameter(s) are chosen, the results and discussion will require updates.

2. Tunnel Conditions

2.1 Tunnel Corridor

The Central corridor and Eastern corridor are presented in Figures 1 and 2, respectively. Both corridors include the same tunnel alignment between the intakes and the tunnel double launch shaft site at the Twin Cities Complex and the same tunnel alignment between the Southern Forebay and the approach channels for Banks and Jones.

The tunnel invert elevations of the two corridors are similar and are in close proximity to each other and would be excavated in similar geologic conditions. Attachment 1 provides the preliminary tunnel plan and profiles used for this TM.

2.2 Geological Conditions

Based on information provided in the *Conceptual Engineering Report* (CER) (DWR, 2018), it is anticipated that the tunnels would be excavated in saturated soft ground conditions. Based on the data previously collected within the potential tunnel alignments or corridors and the anticipated depth of the proposed tunnels, it is expected the soil deposits around the tunnel would consist of clays, silts, silty and clayey sands, and clean sands (DWR, 2018). The groundwater table is expected to be at depths less than 15 feet from existing ground surface. Additionally, some organic materials (primarily peat) could be encountered near the ground surface during shaft excavation. This information was based on a limited number of borings that were done primarily along the Central Corridor (DWR, 2018) and would need be confirmed by future field investigations. It is expected that the geology would vary over the very long tunnel alignments.

2.3 Tunnel Excavation and Ground Support Assumptions

The settlement analysis assumes the tunnel would be excavated with a pressurized face tunnel boring machine (TBM) using either an earth pressure balance machine, a slurry shield, or a hybrid with a minimal overcut. The analysis further assumes the ground would be supported with bolted and gasketed precast concrete tunnel segments. The tunnel segments are assumed to be erected as close as possible within the tunnel tail shield, and the annular space outside the tunnel segments would be backfill grouted closely after segment erection.

3. Settlement Approach and Key Parameters

3.1 Settlement Approach

Settlement in soft ground caused by tunneling generally occurs in the form of a symmetrical trough, centered about the tunnel centerline. The settlement trough shape is approximated as an inverted Gaussian normal distribution curve (Figure 3). The total area under the curve represents the volume loss due to tunneling, typically expressed as a percentage of the total tunnel excavation volume.

The actual settlement along the corridor would vary and be governed by factors such as final TBM configuration, ground and groundwater conditions, depth of tunnel the operation of the TBM, and the construction methods.

Figure 3. Generalized Settlement Trough due to Tunneling (Mair, 1998)

Along the Central and Eastern corridors, it appears that the tunnel would cross most utilities in a generally perpendicular direction. Ground settlements for these utilities would take a shape similar to that shown on Figure 3. There do not appear to be significant utilities that run approximately parallel to the tunnel within the width of the settlement trough. However, there are some locations where the tunnel runs approximately parallel to canal levees. Utilities or levees that do run parallel to the corridor, would experience a settlement profile similar to what is shown on Figure 4.

Figure 4. Settlement Trough for Utilities Parallel to the Tunnel (Mair, 1998)

3.2 Key Parameters

3.2.1 Tunnel Excavation Diameter

The excavation diameter is used, in part, to calculate the total soil volume loss that occurs during tunnel excavation. The excavated tunnel diameter is based on the tunnel's finished inside diameter, segment

thickness, and overcut. The range of finished inside tunnel diameters considered in this TM include 26, 31, 36, and 40 feet. The thickness of the segments would vary, depending on the finished inside diameter of the tunnel, as well as the structural design. To facilitate segment erection, steering tolerances and shield thickness the excavated diameter is slightly larger than the outside diameter of the precast segments. This over excavation is referred to as the overcut. Table 1 shows the assumed segment thicknesses, overcut, and corresponding excavation diameter used for this analysis. Generally, all other factors remaining constant, larger tunnel diameters would result in larger maximum settlement values and wider settlement troughs.

Table 1. Tunnel Excavation Diameters for Various Tunnel Sizes

Finished Inside Diameter (ft)	Segment Thickness ^a (in)	Overcut ^b (in)	Excavation Diameter (ft)
26	14	5	29.2
31	16	6	34.7
36	18	7	40.2
40	24	8	45.3

^a Based on Conceptual Tunnel Lining Evaluation (DCA, 2021)

^b Assumed overcut is on the tunnel radius

Notes:

ft = foot (feet)

in = inch(es)

3.2.2 Tunnel Depth

For this preliminary settlement analysis presented in this TM, ground surface settlements were estimated for the current tunnel profile (Attachment 1), along with raising the tunnel by 10, 20, and 30 feet, respectively. Generally, as the tunnel depth decreases the maximum settlement value increases and the settlement trough width decreases.

3.2.3 Volume Loss

This settlement analysis assumes the tunnel would be excavated using a pressurized face TBM. Recent projects constructed around the world have reported volume losses between 0.15 percent and 1.5 percent for pressurized face tunnels, with most reporting volume losses between 0.25 percent and 0.5 percent (ITA, 2007). This typical range is representative of volume losses anticipated for this Project. Settlement values presented within this TM are based on a volume loss of 0.25 percent, as that value was estimated to provide the most realistic results. Settlement values for a volume loss of 0.5 percent are included in the tables presented in Attachment 2. Generally, the greater the volume loss, the larger the total settlement and the settlement trough width.

3.2.4 Trough Width Parameter

The transverse distance from the tunnel centerline to the inflection point, ($i=Kz$) is characterized by a trough width factor (K) and the depth to the tunnel springline (z). The trough width factor K is a function of ground type. The ranges of recommended K values are 0.2 to 0.3 for sands above the groundwater table, and 0.4 to 0.7 for hard to soft clays (O'Reilly and New, 1982). For sands below the groundwater

level, the K factor ranges from 0.2 to 0.6, depending on the ratio of tunnel depth to tunnel diameter (Peck, 1969). As discussed, the ground conditions for this project consist of layers of saturated clay, silt, silty and clayey sands, and clean sands. A trough width parameter of 0.5 was used to represent the clays. The trough width parameter for the sands below the water table was determined to be 0.5 based on the guidance provided by Peck (1969). A copy of the calculation to determine the trough width parameter for the sands is provided in Attachment 2. Typically, larger trough width parameters result in wider overall settlement troughs with lower maximum settlement values.

4. Critical Settlement Analysis Locations

Several locations along both corridors have been identified as critical related to settlement due to the presence of existing infrastructure. Settlements were estimated at locations along each corridor where the minimum and maximum tunnel depths would be encountered. The minimum tunnel depth generally results in the largest surface settlement along the corridor, while the maximum tunnel depth generally results in the widest settlement trough along the corridor.

4.1 Central Corridor

4.1.1 East Bay Municipal Utility District's Mokelumne Aqueducts

The Central corridor tunnel would cross the Mokelumne Aqueducts at approximately tunnel Station 1900+00. At that location, two of the aqueducts are located above ground surface and rest on pipe saddles that are supported on piles. The aqueduct piles at this location have a minimum tip elevation of approximately -50 feet. The third aqueduct is underground at this location as it approaches the Old River crossing. At the approximate Central corridor tunnel crossing location, the invert of the third aqueduct is approximately Elevation -30 feet (EBMUD, 1966). The Central corridor tunnel excavation crown (top of the tunnel) near Station 1900+00 would be approximately at Elevation -120 feet. This would result in approximately 90 feet of cover between the tunnel springline (the widest point of the tunnel, and generally, the mid-point of the tunnel diameter) and the bottom of the Mokelumne Aqueduct piles.

4.1.2 Stockton Deep Water Ship Canal

The Central corridor tunnel would cross the Stockton Deep Water Ship Canal at approximately Station 1465+00. The bottom of the canal would be at approximately Elevation -35 feet. The tunnel excavation crown would be at approximately Elevation -120 feet. This results in approximately 105 feet of clearance between the tunnel springline and the bottom of the canal. The clearance between the tunnel crown and bottom of the canal would be approximately 85 feet. This distance would exceed the minimum clearance of 75 feet required by the Port of Stockton.

4.1.3 Agricultural Canals

The Central corridor tunnel would cross several agricultural canals along the corridor. The canals consist of artificial levees, generally built up to between Elevation 10 feet and Elevation 20 feet, with water flowing within the levees. The levees are constructed with fill material placed on the existing ground surface. The critical component of the canals are the foundations for the levees, which are assumed to be located at the surrounding ground level. Generally, the ground level around the levees is between approximately Elevation -10 feet and Elevation -20 feet. This would result in a minimum soil cover between the tunnel springline and the levee foundation of approximately 105 feet.

4.1.4 Railroad Line

The Central corridor tunnel would cross the Antioch-Stockton rail line, which is owned and operated by BNSF Railway Company (BNSF) near approximately tunnel Station 1893+00. The rail line is actively used for transporting cargo into and out of the Bay Area and is also used by Amtrak. The railroad tracks at this location are supported on pile foundations. At this time, the pile tip elevations are unknown. For this TM, it was assumed that the pile tips extend to Elevation -60 feet. The tunnel excavation crown at this location would approximately be located at Elevation -122 feet. This would result in approximately 80 feet of cover between the pile tips and the tunnel springline.

4.1.5 Roadways

The Central corridor tunnel would cross under two key well-traveled roadways: State Routes 4 and 12. The two roadways are supported on compacted native material. Table 2 summarizes the tunnel crossing beneath the roadways.

Table 2. Tunnel Roadway Crossings Summary

Roadway	Approximate Tunnel		Approximate Ground Surface Elevation	Approximate Depth to Springline (ft)
	Station	Crown Elevation		
State Route 4	2085+00	-125	-10	135
State Route 12	1258+00	-115	-15	120

Note:

ft = foot (feet)

4.1.6 Natural Gas Pipelines

The Central corridor tunnel would cross several natural gas pipelines between approximately Station 946+40 and Station 1770+00. The tunnel would also be located within an area of natural gas fields with hundreds of active and inactive wells. Currently, it is not anticipated that the tunnel would pass near any active wells where the surface equipment would be impacted by settlement. The gas lines are assumed to be located near the surface, with invert depths of less than 10 feet and pipe diameters less than 24 inches. The most conservative scenario for tunnel settlement would be for a location with the least cover between the gas pipeline and the tunnel, which occurs near approximately Station 1100+00, where the ground surface elevation is approximately -20 feet. At this location, the tunnel crown would be approximately at Elevation -120 feet, resulting in approximately 110 feet of cover between the tunnel springline and the theoretical invert of the gas pipeline.

4.1.7 Other Key Project Locations

Another consideration would be for the tunnel alignment near irrigation canals.

- The shallowest depth of cover over the tunnel crown outside of irrigation canals would be located at approximately Station 1400+00. At this location, the depth of cover would be approximately 120 feet to the tunnel springline. This location could represent the maximum settlement for near surface utilities.

- The greatest depth of cover over the tunnel crown not near irrigation canals appears near tunnel Station 450+00. At this location, the depth of cover to the tunnel springline would be approximately 140 feet. This location would represent the widest settlement trough along the corridor.

4.2 Eastern Corridor

4.2.1 East Bay Municipal Utility District's Mokelumne Aqueducts

The Eastern corridor tunnel would cross the Mokelumne Aqueducts at approximately tunnel Station 1965+00. At that location, all three aqueducts are above the ground surface and sitting on pipe saddles that are supported on piles. The piles at this location have a tip elevation of approximately -60 feet. The tunnel excavation crown at this location would be approximately Elevation -120 feet. This would result in approximately 80 feet of cover between the pile tips and the tunnel springline.

4.2.2 Stockton Deep Water Ship Canal

The Eastern corridor tunnel would cross the Stockton Deep Water Ship Canal at approximately Station 1667+00. The bottom of the canal is at approximately Elevation -35 feet. The tunnel excavation crown would be located at approximately Elevation -120 feet. This would result in approximately 105 feet of clearance between the bottom of the canal and the tunnel springline and 85 feet of clearance between the tunnel crown and the bottom of the canal. This separation would exceed the minimum clearance of 75 feet required by the Port of Stockton

4.2.3 Agricultural Canals

The Eastern corridor tunnel would cross several agricultural canals. The canals consist of artificial levees, generally built up to between Elevation 10 feet and Elevation 20 feet with water flowing within the levees. The levees are constructed with fill material placed on the existing ground surface. The critical component of the canals are the foundations for the levees, which are assumed to be located at the surrounding ground level. Generally, the ground level around the levees is at approximately Elevation -10 feet. This would result in approximately 128 feet of cover between the tunnel springline and the levee foundations.

4.2.4 Railroad Lines

The Eastern corridor tunnel would cross beneath the Antioch-Stockton rail line, which is owned and operated by BNSF near tunnel Station 1960+00. The rail line is actively used for transporting cargo into and out of the Bay Area and is also used by Amtrak. Based on historical information, the railroad is constructed at grade at approximately Elevation -10 feet. The tunnel excavation crown at this location would be approximately Elevation -122 feet. This would result in a depth of cover of approximately 132 feet to the tunnel springline.

4.2.5 Roadways

The Eastern corridor tunnel would cross under two key well-traveled roadways: State Routes 4 and 12. The two roadways are supported on compacted native material. Table 3 summarizes the tunnel crossing beneath the roadways.

Table 3. Tunnel Roadway Crossings Summary

Roadway	Approximate Tunnel		Approximate Ground Surface Elevation	Approximate Depth to Springline (ft)
	Station	Crown Elevation		
State Route 4	2230+00	-125	-10	135
State Route 12	1225+00	-115	0	135

Note:

ft = foot (feet)

4.2.6 Natural Gas Pipelines

The Eastern corridor tunnel would cross several gas lines north of approximately tunnel Station 1067+00. The tunnel would also be located within an area of natural gas fields with hundreds of active and inactive wells. Currently, it is not anticipated that the tunnel will pass near any active wells where the surface equipment would be impacted by settlement. The gas lines are assumed to be near the surface, with invert depths of less than 10 feet and pipe diameters less than 24 inches. The tunnel excavation crown elevation near the gas lines would be approximately Elevation -115 feet. The cover between the tunnel springline and the bottom of the pipe would be approximately 125 feet.

4.2.7 Overhead High-voltage Electrical Transmission Line

The Eastern corridor tunnel would cross a high-voltage electrical transmission line near approximately tunnel Station 869+00 and multiple lines north of the Mokelumne River. The pole foundation types and depths are not known at this time; nor are the specific pole locations relative to the tunnel corridor. For this TM, it was conservatively assumed that the towers are located along the tunnel centerline and supported on deep foundations extending 50 feet below grade. The ground surface elevation in these ranges varies between approximately Elevation 0 feet and 10 feet. Therefore, it is assumed that the base of the deep foundations is at Elevation -50 feet. The tunnel excavation crown would be located at approximately Elevation -112 feet; therefore, there would be approximately 82 feet of soil between the tunnel springline and the base of the foundation.

4.2.8 Other Key Project Locations

Another consideration would be for the tunnel alignment near irrigation canals.

- The shallowest depth of cover over the tunnel crown outside of irrigation canals would be located at Station 930+00. At this location, the depth of cover would be approximately 125 feet to the tunnel springline. This location could represent the maximum settlement for near-surface utilities.
- The greatest depth of cover over the tunnel crown not near irrigation canals appears near tunnel Station 2270+00. At this location, the depth of cover would be approximately 140 feet. This location would represent the widest settlement trough along the corridor.

5. Settlement Results

This section presents the settlement results for the two tunnel corridors without any efforts to reduce the settlement potential. The results represent the maximum anticipated settlement values. Actual

settlement values could be significantly less than those presented with implementation with good construction practices and ground improvement if required.

The tables provided do not include all parameter combinations. The values presented in the following table are based on a volume loss of 0.25 percent. Note, the calculated settlement trough widths do not include ground surface settlements less than 1/8-inch. Attachment 2 provides the complete results.

5.1 Central Corridor

Tables 4 and 5 summarize the settlement results for the Central corridor. Table 4 shows the variability in the settlement and trough width for the multiple tunnel sizes considered, while Table 5 shows the same for the multiple tunnel depths considered.

Notes:

EBMUD = East Bay Municipal Utilities District

ft = foot (feet)

in = inch(es)

The settlement results in Table 4 indicate maximum settlement at the current tunnel depth and would range from 0.11 to 0.20 inches for the 26-foot-diameter tunnel to 0.28 to 0.48 inches for the 40-foot-diameter tunnel. Settlements for the 36-foot-diameter tunnel, as shown in Table 5, would range from 0.23 to 0.43 inches at the current depth to 0.28 to 0.61 inches at the proposed tunnel depth raised by 30 feet.

5.2 Eastern Corridor

Tables 6 and 7 summarize the settlement results for the Eastern corridor. Table 6 shows the variability in the settlement and trough width for the multiple tunnel sizes considered, while Table 7 shows the same for the multiple tunnel depths considered.

Notes:

EBMUD = East Bay Municipal Utilities District

ft = foot (feet)

in = inch(es)

The settlement results in Table 6 indicate maximum settlement at the current tunnel depth would range from 0.11 to 0.20 inches for the 26-foot-diameter tunnel to 0.28 to 0.47 inches for the 40-foot-diameter tunnel. Settlement for the 36-foot diameter tunnel, as shown in Table 7, would range from 0.23 to 0.43 inches at the current depth. Settlement results for the 36-foot diameter tunnel would range from 0.28 to 0.61 inches if the tunnel depth was raised by 30 feet.

6. Allowable Settlements

The preliminary assessment includes the estimates of free-field settlements caused by the underground construction. The purpose of this preliminary analysis is to evaluate anticipated ground movements so that potential construction methods could be identified to minimize settlement. In this preliminary assessment, limits of the trough width are established, and any structures located outside this zone require no further future assessment. The stages that follow are usually structure-specific and would be performed in future when site specific geotechnical information becomes available and the maximum settlement criteria that would be acceptable by the owners of the various structures/features in question.

7. Methods to Reduce Settlement Potential

7.1 Settlement Monitoring

During construction, a robust settlement monitoring program should be developed to monitor ground movements as the tunnel advances. The information gained during the initial stages of this monitoring program could be used to refine TBM operational techniques, as well as future settlement predictions.

The settlement monitoring program would likely consist of some combination of the following instruments.

- **Ground monitoring points** – Settlement monitoring point installed in the ground to detect ground movement. These can be located above utilities at shallow depths, directly adjacent to utilities and installed near the utility invert elevation, or at the foundation level of key infrastructure. Ground monitoring points typically consist of placing a steel rod inside a drilled hole that is cased and grouted. The steel rod is then monitored for movement. The spacing and frequency of these monitoring points typically depend on the ground conditions, and the surface and near-surface features.
- **Utility monitoring points** – Settlement monitoring point that is placed directly on top of a utility to specifically monitor movement in an individual utility. These monitoring points typically are similar to the ground monitoring points. For utilities running perpendicular to the tunnel corridor, utility monitoring points can be placed across the utility at defined intervals within the anticipated settlement trough width to determine the extent of movement that occurred across the utility. Utilities that run perpendicular to the tunnel often have monitoring points spaced equally along the utility, as long as it is within the anticipated tunnel settlement trough. The actual spacing of utility monitoring points would depend on the existing condition of the utility, the importance of the utility, the estimated settlement, and the availability of surface access.
- **Extensometers** – Settlement monitoring anchor that measures displacement continuously via a reference head located at the ground surface. Extensometers are typically installed within a drilled hole and grouted in-place. Multiple extensometers can be installed within a borehole to measure displacements at multiple elevations.
- **Structure monitoring points** – Monitoring points can be placed directly on aboveground infrastructure to monitor them for movement. These monitoring points can be as simple as survey targets that are surveyed using traditional surveying techniques to liquid-leveling sensors that are strung along a structure that continually monitor and report movement. For this Project, it is anticipated that, at a minimum, the EBMUD Mokelumne Aqueducts, rail lines, and overhead transmission power lines would require structure monitoring points.

In addition to the settlement monitoring techniques described, the TBM and trailing gear can be designed to alert the operator when the conditions for ground settlement are occurring. For example, scales or lasers can be used to monitor the volume of material being removed by the conveyor belt on the TBM. If over excavation were to occur, a likely indication of future settlement, the operator would be notified and TBM performance could be altered. Regardless of the settlement monitoring means, the settlement monitoring data should be continuously monitored during construction, and TBM operations modified should unanticipated settlements occur.

7.2 Ground Improvement

Should unacceptable settlements of any utilities or structures be anticipated, the settlement risk could be reduced prior to tunnel excavation. There are several different methods that can be used to either reduce the potential settlement of a utility/structure or reduce the potential impact settlement would have on the utility. The final selection of the best options for each location will be determined following additional geotechnical investigations.

For this Project, the number of utilities and structures that the tunnel crosses are limited and widely spaced. As a result, the settlement of utilities along the tunnel corridors could be reduced, if required, by grouting the ground between the tunnel crown and the invert of the utility and foundation before tunnel

excavation and sometimes after tunneling if the actual ground losses are deemed to be excessive despite all efforts to minimize ground loss. Grouting effectively reduces settlement by strengthening the ground so the soil can support higher loads before deforming and by reducing the likelihood of over-excavation, which can lead to settlement. The following grouting methods are anticipated to be feasible for this Project:

- Jet grouting
- Compaction grouting
- Permeation grouting
- Compensation grouting

Jet grouting involves injecting grout into the ground under high pressure. Once the hole is drilled, the grout, which is typically cementitious, is injected in a circular motion as the drill string is slowly raised. The grout erodes and mixes in with the soil, creating a column of strengthened ground. Jet grouting is more effective in granular soils, because they are more erodible than cohesive soils.

Compaction grouting densifies the soil by injecting a stiff grout into the ground to compact and displace the existing soil. Compaction grout is injected under high pressure in a vertical or inclined hole, to create a spherical of compacted soil around the hole. Compaction grouting is typically performed in fine-grained soils with cementitious grouts.

Permeation grouting works by filling the pore space in granular soils with grout to create a strengthened soil mass. Therefore, it does not work well in soils with a large percentage of fine material. Using this method, the grout is injected at lower pressures to not disturb the soil. This method works well with both cementitious and chemical grouts.

Compensation grouting requires injecting cementitious grout under high pressures to create fractures in the soil matrix, which are filled with grout. The grout compacts the soil surrounding the fracture creating strengthened seams of soil. The grout injection locations are controlled by injecting the grout through sleeve port pipes. Compensation grouting is commonly used to mitigate settlements that have occurred since the ground heaves when the fractures are opened allowing infrastructure to be re-leveled. The primary advantage of compensation grouting is that it can be performed in almost any soil condition.

7.3 Utility Relocation and Rehabilitation

If a utility within the tunnel settlement trough can be relocated outside of the settlement trough, that is likely the easiest and most cost-effective method to reduce potential settlement. However, this is not always possible due to existing surface and near-surface features and the utility alignment.

Existing utilities that are susceptible to damage from settlement can be relined with a material that will allow greater movement. This is often performed on utilities that are deteriorating or were originally constructed of materials, such as brick or cast-iron, which do not allow much deflection before cracking or failing. There are multiple materials and techniques that can be used to re-line utilities. However, all methods reduce the effective of the pipeline cross section, thus potentially reducing its capacity.

8. Vibrations Due to TBM Operations

Ground vibrations are primarily a function of the excavation method and geologic conditions. Vibrations generated by TBM excavation are typically extremely low and rarely cause damage to surface structures. The peak particle velocity produced is a commonly used parameter to measure the potential risk for

building damage from construction activities such as TBM operations. Typically, vibrations exceeding about 0.02 to 0.03 inches per second were found to be noticeable and potentially disturbing (Oriard, 1972). Previous studies indicate that humans can detect steady state vibrations as low as about 0.01 inches per second in terms of peak particle velocity (Flanagan, 1993; Siskind, D.E., et al., 1980).

For the conceptual design effort, an evaluation of the vibration was made based on attenuation curves developed for variety of types of construction equipment, as shown on Figure 5. One of the curves show the relationship between peak particle velocity and resultant distance from the TBM (soil). Based on the current tunnel profiles shown on the drawings a minimum ground cover of 110 feet (33.5 m) can be expected along the main tunnel alignment for the central and eastern alternatives. Based on the current minimum ground cover a peak particle velocity of 0.003 inches per second (0.07 mm/s) can be expected. Assuming that humans can detect vibrations equal to or greater than 0.01 inches per second, it appears unlikely there will be that noticeable vibrations will be generated along the main tunnel alignment. Further evaluations of the vibrations will be made during final design.

9. Sound Pressure Level Prediction at San Joaquin River Crossing

The groundborne vibration (GBV) in soil and sound pressure level (SPL) in water due to the operation of a tunnel boring machine (TBM) for the Project were predicted at the San Joaquin River crossing. The factors which influence the generation and propagation of groundborne vibration from TBMs are primarily the amount of energy required to cut the soil and the propagation characteristics of the soil. Rotational speed, cutter head type and face pressure have a much smaller effect. The energy requirement is a function of the tunnel diameter and the operating characteristics of the machine.

The prediction of groundborne vibration from TBMs begins with measured field data obtained on other TBM projects. For this evaluation, a recent California tunneling project, the Los Angeles (LA) Metro Red Line Section 2 (HMMH, 1993) was used in the computations for predicting the GBV and SPL. The geotechnical conditions at the Project tunnel depth are expected to consist of saturated soils comprising of clays, silts, silty and clayey sands, and clean sands based on the data previously collected and are similar to the LA Metro Red Line Section 2 ground conditions. A 21-foot shielded TBM was used to excavate the LA Metro Red Line tunnels and due to the smaller diameter, a correction factor was applied to account for the larger 40-foot diameter TBM that would be used on the Project. The LA Metro Red Line Tunnels were excavated 43 feet below ground surface at the location where the vibration measurements were recorded compared 68 feet below the analysis point for the San Joaquin River Crossing.

To predict TBM induced vibration levels, the 1993 LA Metro Red Line measured TBM reference levels at a known distance were extrapolated using the 2011/2016 measured attenuation profiles from borehole vibration propagation test performed in the area of the Westside Purple Line Extension- Section 3 tunnel alignment. Six borehole measurements performed by ATS Consulting in 2011 and 2016 (ATS Consulting 2011, 2016) were utilized to determine the effective attenuation rates of propagating waves along the alignment. The borehole vibration propagation tests followed the Detailed Assessment approach recommended in the Federal Transit Administration (FTA) guidance manual (FTA, 2018). The relationship shown below (WSP, 2020) was used to make the predictions for the RMS vibration velocity L_v at the bottom of the San Joaquin River Channel.

Where:

$$L_v = L_{v0} + \alpha \times \log_{10} (R/R_0)$$

L_v = Predicted vibration level at the bottom of the San Joaquin River Channel

L_{v0} = 1993 measured reference RMS velocity in dB re: 1 micro-inch/sec.

R_o = Source to vibration sensor distance for L_{vo} in feet

R = Source to receiver distance for predicted level L_v in feet

$\alpha \times \log_{10} (R/R_o) = 2011/2016$ measured composite attenuation rate

Underwater sound pressure levels (SPL) often are expressed in decibels (dB). The decibel is used for many different engineering applications, and it is commonly used to describe the magnitude of a sound pressure. It is a convenient way of expressing sound pressure level because the sound pressure is typically a result of a very wide range of pressures. The relationship shown below (Caltrans, 2020) was used to make the prediction for the SPL in water at the bottom of the San Joaquin River Channel.

$$SPL_{water} = SPL_{air} + 26 \text{ dB}$$

The SPL predicted at the San Joaquin River Crossing is summarized below.

Top of Tunnel to River Channel Bottom	68 feet
Sound Pressure Level (SPL) in Soil	72 dB
Adjustment for 20 to 40-foot diameter TBM	6 dB
Adjusted Sound Pressure Level in Soil	78 dB
Caltrans Conversion from soil SPL to water SPL	26 dB
Adjusted SPL in Water	104 dB

10. Conclusion

The data presented in this TM are based on limited geotechnical information and conceptual engineering-level data. Once the tunnel corridor, diameter, and invert elevations are established and site-specific geotechnical conditions are determined at the key project locations, this information will be updated to reflect ground conditions encountered during the geotechnical investigation program.

In a few locations, specific methods to reduce settlement potential are anticipated to be required, especially at the EBMUD Mokelumne Aqueducts crossing locations on the Central and Eastern corridors and at the railroad crossing location on the Central corridor.

An allowable settlement criterion would be established for each utility along the corridor, in partnership with the utility owner.

A Project-specific instrumentation monitoring program would be developed, considering the requirements of all the Project participants, the public, and third parties. The monitoring program would be used during construction to monitor the performance of the construction and adjust TBM operations to limit settlement.

Estimated sound pressure level in the water at the bottom of the river channel is not expected to exceed a SPL of 110 dB. The analysis should be revisited once more detailed geotechnical information becomes available at the San Joaquin River Crossing.

Unmitigated Ground Settlement Results

Project Name: Delta Conveyance

Location: Central corridor EBMUD Mokelumne Aqueducts

Approx Station: 1840+00

Purpose: To estimate the surface settlement caused by tunnel excavation

References: Aoyagi, T. (1995) Representing Settlement for Soft Ground Tunneling
California Waterfix (2018) Conceptual Engineering Report Byron Tract Forebay Option
O'Reilly and New (1982) Settlements above tunnels in the United Kingdom - their magnitude and prediction
Peck, R.B. (1969) Deep Excavations and Tunneling in Soft Ground

Assumption(s): Calculated settlement is from construction activities only
Ground conditions are similar to those in the Conceptual Engineering Report

Equations	Maximum Settlement	$S_{\max} = \frac{\sqrt{2} \cdot V_s}{2 \cdot \sqrt{\pi} \cdot i}$
	Settlement Trough Inflection Distance	$i = K \cdot Z$
	Total Settlement Volume	$V_s = V_L \cdot \pi \cdot R^2$
	Settlement at Distance x from Tunnel Centerline	$S = S_{\max} \cdot e^{\left(\frac{-x^2}{2 \cdot i^2} \right)}$

Input Parameter	Symbol	Value	Unit	Notes
Excavated Tunnel Radius	R ₁	14.60	ft	26 ft inside diameter plus segments and excavation overcut
	R ₂	17.35	ft	31 ft inside diameter plus segments and excavation overcut
	R ₃	20.10	ft	36 ft inside diameter plus segments and excavation overcut
	R ₄	22.65	ft	40 ft inside diameter plus segments and excavation overcut
Depth to Excavation Springline	Z ₁	90.10	ft	Depth to springline on plan and profile from pile tip elev -50
	Z ₂	80.1	ft	Raise tunnel 10 feet
	Z ₃	70.1	ft	Raise tunnel 20 feet
	Z ₄	60.1	ft	Raise tunnel 30 feet
Trough Width Parameter	K	0.5	NA	Cohesive soil (O'Reilly and New, 1982) and cohesionless soil below groundwater table (Peck, 1969)
Ground Loss Percent	V _{L1}	0.25%	%	Assumed average value based on recent projects
	V _{L2}	0.50%	%	Assumed max value based on recent projects

Surface Settlement vs Distance from Tunnel Centerline

Project Name: Delta Conveyance

Location: Central corridor Highway 4 crossing

Approx Station: 2032+00

Purpose: To estimate the surface settlement caused by tunnel excavation

References: Aoyagi, T. (1995) Representing Settlement for Soft Ground Tunneling
California Waterfix (2018) Conceptual Engineering Report Byron Tract Forebay Option
O'Reilly and New (1982) Settlements above tunnels in the United Kingdom - their magnitude and prediction
Peck, R.B. (1969) Deep Excavations and Tunneling in Soft Ground

Assumption(s): Calculated settlement is from construction activities only
Ground conditions are similar to those in the Conceptual Engineering Report

Equations	Maximum Settlement	$S_{\max} = \frac{\sqrt{2} \cdot V_s}{2 \cdot \sqrt{\pi} \cdot i}$
	Settlement Trough Inflection Distance	$i = K \cdot Z$
	Total Settlement Volume	$V_s = V_L \cdot \pi \cdot R^2$
	Settlement at Distance x from Tunnel Centerline	$S = S_{\max} \cdot e^{\left(\frac{-x^2}{2 \cdot i^2} \right)}$

Input Parameter	Symbol	Value	Unit	Notes
Excavated Tunnel Radius	R ₁	14.60	ft	26 ft inside diameter plus segments and excavation overcut
	R ₂	17.35	ft	31 ft inside diameter plus segments and excavation overcut
	R ₃	20.10	ft	36 ft inside diameter plus segments and excavation overcut
	R ₄	22.65	ft	40 ft inside diameter plus segments and excavation overcut
Depth to Excavation Springline	Z ₁	135.10	ft	Depth to springline on plan and profile
	Z ₂	125.1	ft	Raise tunnel 10 feet
	Z ₃	115.1	ft	Raise tunnel 20 feet
	Z ₄	105.1	ft	Raise tunnel 30 feet
Trough Width Parameter	K	0.5	NA	Cohesive soil (O'Reilly and New, 1982) and cohesionless soil below groundwater table (Peck, 1969)
Ground Loss Percent	V _{L1}	0.25%	%	Assumed average value based on recent projects
	V _{L2}	0.50%	%	Assumed max value based on recent projects

Surface Settlement vs Distance from Tunnel Centerline

Project Name: Delta Conveyance

Location: Central corridor deepest tunnel cover

Approx Station: 470+00

Purpose: To estimate the surface settlement caused by tunnel excavation

References: Aoyagi, T. (1995) Representing Settlement for Soft Ground Tunneling
California Waterfix (2018) Conceptual Engineering Report Byron Tract Forebay Option
O'Reilly and New (1982) Settlements above tunnels in the United Kingdom - their magnitude and prediction
Peck, R.B. (1969) Deep Excavations and Tunneling in Soft Ground

Assumption(s): Calculated settlement is from construction activities only
Ground conditions are similar to those in the Conceptual Engineering Report

Equations	Maximum Settlement	$S_{\max} = \frac{\sqrt{2} \cdot V_s}{2 \cdot \sqrt{\pi} \cdot i}$
	Settlement Trough Inflection Distance	$i = K \cdot Z$
	Total Settlement Volume	$V_s = V_L \cdot \pi \cdot R^2$
	Settlement at Distance x from Tunnel Centerline	$S = S_{\max} \cdot e^{\left(\frac{-x^2}{2 \cdot i^2} \right)}$

Input Parameter	Symbol	Value	Unit	Notes
Excavated Tunnel Radius	R ₁	14.60	ft	26 ft inside diameter plus segments and excavation overcut
	R ₂	17.35	ft	31 ft inside diameter plus segments and excavation overcut
	R ₃	20.10	ft	36 ft inside diameter plus segments and excavation overcut
	R ₄	22.65	ft	40 ft inside diameter plus segments and excavation overcut
Depth to Excavation Springline	Z ₁	140.10	ft	Depth to springline on plan and profile
	Z ₂	130.1	ft	Raise tunnel 10 feet
	Z ₃	120.1	ft	Raise tunnel 20 feet
	Z ₄	110.1	ft	Raise tunnel 30 feet
Trough Width Parameter	K	0.5	NA	Cohesive soil (O'Reilly and New, 1982) and cohesionless soil below groundwater table (Peck, 1969)
Ground Loss Percent	V _{L1}	0.25%	%	Assumed average value based on recent projects
	V _{L2}	0.50%	%	Assumed max value based on recent projects

Surface Settlement vs Distance from Tunnel Centerline

Project Name: Delta Conveyance

Location: East corridor rail road crossing

Approx Station: 1900+00

Purpose: To estimate the settlement caused by tunnel excavation

References: Aoyagi, T. (1995) Representing Settlement for Soft Ground Tunneling
California Waterfix (2018) Conceptual Engineering Report Byron Tract Forebay Option
O'Reilly and New (1982) Settlements above tunnels in the United Kingdom - their magnitude and prediction
Peck, R.B. (1969) Deep Excavations and Tunneling in Soft Ground

Assumption(s): Calculated settlement is from construction activities only
Ground conditions are similar to those in the Conceptual Engineering Report

Equations Maximum Settlement
$$S_{\max} = \frac{\sqrt{2} \cdot V_s}{2 \cdot \sqrt{\pi} \cdot i}$$

Settlement Trough Inflection Distance
$$i = K \cdot Z$$

Total Settlement Volume
$$V_s = V_L \cdot \pi \cdot R^2$$

Settlement at Distance x from Tunnel Centerline
$$S = S_{\max} \cdot e^{\left(\frac{-x^2}{2 \cdot i^2} \right)}$$

Input Parameter	Symbol	Value	Unit	Notes
Excavated Tunnel Radius	R ₁	14.60	ft	26 ft inside diameter plus segments and excavation overcut
	R ₂	17.35	ft	31 ft inside diameter plus segments and excavation overcut
	R ₃	20.10	ft	36 ft inside diameter plus segments and excavation overcut
	R ₄	22.65	ft	40 ft inside diameter plus segments and excavation overcut
Depth to Excavation Springline	Z ₁	132.10	ft	Depth to springline on plan and profile

Surface Settlement vs Distance from Tunnel Centerline

Project Name: Delta Conveyance

Location: East corridor overhead electrical transmission line crossing

Approx Station: 810+00

Purpose: To estimate the settlement caused by tunnel excavation

References: Aoyagi, T. (1995) Representing Settlement for Soft Ground Tunneling
 California Waterfix (2018) Conceptual Engineering Report Byron Tract Forebay Option
 O'Reilly and New (1982) Settlements above tunnels in the United Kingdom - their magnitude and prediction
 Peck, R.B. (1969) Deep Excavations and Tunneling in Soft Ground

Assumption(s): Calculated settlement is from construction activities only
 Ground conditions are similar to those in the Conceptual Engineering Report

Equations

Maximum Settlement
$$S_{\max} = \frac{\sqrt{2} \cdot V_s}{2 \cdot \sqrt{\pi} \cdot i}$$

Settlement Trough Inflection Distance
$$i = K \cdot Z$$

Total Settlement Volume
$$V_s = V_L \cdot \pi \cdot R^2$$

Settlement at Distance x from Tunnel Centerline
$$S = S_{\max} \cdot e^{\left(\frac{-x^2}{2 \cdot i^2} \right)}$$

Input Parameter	Symbol	Value	Unit	Notes
Excavated Tunnel Radius	R_1	14.60	ft	26 ft inside diameter plus segments and excavation overcut
	R_2	17.35	ft	31 ft inside diameter plus segments and excavation overcut
	R_3	20.10	ft	36 ft inside diameter plus segments and excavation overcut
	R_4	22.65	ft	40 ft inside diameter plus segments and excavation overcut
Depth to Excavation Springline	Z_1	82.10	ft	Depth to springline on plan and profile from pile tip elev (EL -50)

Surface Settlement vs Distance from Tunnel Centerline

Purpose

To determine the trough width parameter for granular soils beneath the groundwater table

Reference

Peck, R.B. (1969). Deep Excavations and Tunnels in Soft Ground. Proceedings of the 7th International Conference on Soil Mechanics and Foundation Engineering.

Inputs

Approximate average tunnel depth at springline

$$z := 130 \text{ ft}$$

Tunnel excavation radius for 36-foot ID tunnel

$$r := 19.915 \text{ ft}$$

Ratio of tunnel depth over diameter

$$\text{Ratio}_z := \frac{z}{2 \cdot r} = 3.264$$

Ratio of inflection point over radius (Fig 9)

$$\text{Ratio}_i := 3.25$$

Fig. 9 Relation Between Width of Settlement Trough, as Represented by i/R , and Dimensionless Depth of Tunnel, $z/2R$, for Various Tunnels in Different Materials

Inflection point

$$i := \text{Ratio}_i \cdot r = 64.724 \cdot \text{ft}$$

Settlement trough parameter

$$k := \frac{i}{z} = 0.498$$
